The Fork in the Road: How LibreOffice Was Born from a Crisis of Trust

A Case Study in Open Source Governance, Community, and the Ethics of Control

Section A	Establishing the Context

A.1 The Stage Before the Storm

To understand why LibreOffice exists, you have to appreciate what the computing landscape looked like at the turn of the millennium. Microsoft Office was not simply popular — it was infrastructural. Governments drafted legislation in Word, universities submitted budgets in Excel, and the underlying file formats were deliberately proprietary, creating a technological moat that forced anyone wanting to exchange documents to pay for the same toolchain. For institutions in developing economies or with tight public budgets, this was less a product choice and more an imposed tax.

Into this landscape stepped Sun Microsystems in 1999, acquiring Star Division and open-sourcing its StarOffice suite under the name OpenOffice.org. The move was strategically motivated — Sun wanted to weaken Microsoft's grip on the desktop — but its practical effect was genuinely liberating. A credible, cross-platform office suite was now freely available, readable in any language, and modifiable by anyone. Tens of millions of users adopted it; governments from Brazil to Germany considered mandating it; an active volunteer community of developers, translators, and documentation writers gave it life.

A.2 The Structural Fault Beneath the Surface

> *The critical insight: OpenOffice.org was open source in its licensing but not in its governance. These two things are related but not identical, and conflating them was the community's most consequential blind spot.*

Sun required every contributor to sign a Joint Copyright Assignment agreement. This meant that code written by a volunteer in Hyderabad on a Sunday afternoon — debugged, tested, and submitted for free — became the joint intellectual property of Sun Microsystems the moment it was merged. The contributor retained a theoretical right to their work, but Sun held practical authority: it could license that code commercially, change the project's direction, or hand it to a successor company without asking anyone's permission.

Beyond copyright, Sun controlled release schedules, roadmaps, and final acceptance of features. Community proposals could be built, polished, and submitted — and then shelved because a Sun product manager decided it did not align with quarterly priorities. Development was measurably slower than comparable community-governed projects because every decision had to navigate corporate bureaucracy.

Why did contributors tolerate this? Partly inertia — the project existed and worked. Partly pragmatism — Sun provided servers, legal infrastructure, and full-time developers. And partly because Sun, for all its faults, was a company with genuine sympathy for the open source world. It

had invented Java, championed Unix, and open-sourced Solaris. Its governance of OpenOffice.org was imperfect, but it was not hostile. The community grumbled, but it stayed.

A.3 Oracle: The Trigger That Made the Inevitable Happen

When Oracle acquired Sun in January 2010 for approximately 7.4 billion US dollars, it inherited every Sun asset — including OpenOffice.org, Java, MySQL, and Solaris. Oracle was a fundamentally different kind of company. Its culture was built around aggressive intellectual property protection, enterprise licensing deals, and commercial leverage. It was not hostile to technology — it was one of the world's premier technology firms — but it was hostile to giving things away when those things could generate revenue.

The copyright assignment problem, which had been uncomfortable under Sun, now became genuinely alarming. Contributors had signed away rights to Sun. Those rights now belonged to Oracle. Oracle almost immediately demonstrated its posture: it launched Oracle Open Office — a commercially branded version of the community's work — and filed a high-profile patent and copyright lawsuit against Google over Java's use in Android. The message was unmistakable: Oracle would use intellectual property law as a weapon, and the community had handed Oracle significant IP through years of copyright assignment.

This is why Oracle was the trigger while Sun was not: the underlying structural problem — concentrated governance and mandatory copyright assignment — was the same. But the identity of the controller matters enormously. A landlord who has always been lenient with the lease clauses is manageable. The same lease in the hands of a landlord known for aggressive enforcement is a different situation entirely.

A.4 Legal Openness Versus Practical Openness

The deepest lesson of this period is the gap between what a license promises and what governance delivers. The GNU Lesser General Public License under which OpenOffice.org was distributed guaranteed the four classical software freedoms: to use, to study, to modify, and to redistribute. Every one of those freedoms was real. The community could fork — and eventually did.

But legal freedom is not the same as practical freedom. Forking cost the community years of duplicated effort, confused users, fragmented distributions, and reputational uncertainty. The freedom to fork existed in the license; exercising it exacted a price that a genuinely democratically-governed project would never have imposed. Practical openness requires not just open licensing, but open governance: transparent decision-making, distributed copyright, and no single entity with veto authority.

Section B	The Ethics of Corporate Control

This section engages the central ethical question the case raises: does corporate investment in an open source project justify corporate governance authority over it? I will argue that it does not — at least not in the form that Sun and Oracle exercised — while giving the counterargument its full due.

B.1 The Investment-Entitles-Control Argument

The pro-corporate-control position begins from an obvious premise: infrastructure is not free. Sun paid lawyers to draft the licensing agreements, maintained the servers that hosted the codebase, employed full-time engineers who wrote substantial portions of the code, and provided the organisational continuity that volunteer communities often lack. The copyright assignment clause, on this view, was fair consideration — a mechanism by which Sun recouped some of the value it provided.

There is also an accountability argument. When something goes wrong in a software project — a security vulnerability, a broken release, a licensing dispute — someone must be able to act quickly and decisively. Governance by committee, while democratically appealing, can be paralysingly slow. Centralised authority enables rapid response. This is not merely a cynical corporate position; it is a real operational concern that any large software project must resolve.

Finally, the argument runs: if contributors disliked the terms, they were not compelled to sign. The copyright assignment agreement was disclosed upfront. Nobody joined OpenOffice.org under false pretences. If the terms were exploitative, contributors were free to work elsewhere.

B.2 Why This Argument Ultimately Fails

> *My position: corporate investment earns a seat at the governance table — not the head of the table, and certainly not the only seat. The Sun/Oracle model crossed from stewardship into appropriation.*

The investment argument is strongest at the margins and weakest at the core. Yes, Sun provided infrastructure. But by the mid-2000s, the OpenOffice.org community had grown far beyond what Sun's investment could claim to have created. The project's value — its translations into dozens of languages, its user base in developing nations, its compatibility improvements, its documentation — was overwhelmingly produced by people who received nothing in return except the satisfaction of contributing. Sun's initial investment had been repaid many times over in community labour. The intellectual property claim that copyright assignment created was disproportionate to the ongoing contribution.

The accountability argument has more merit but also has a ready answer: the Document Foundation solved exactly this problem. LibreOffice has a legal entity — a German Stiftung — that can sign contracts, hold trademarks, respond to security issues, and make decisions. It does so

through elected committees rather than corporate hierarchy. Accountability does not require concentrated ownership; it requires clear process. Sun's model conflated the two.

The consent argument — that contributors signed freely — is the weakest of the three. It ignores network effects and the cost of exit. A developer who spent three years contributing to OpenOffice.org before the Oracle acquisition had not simply agreed to terms; they had built relationships, reputation, and deep knowledge of a specific codebase. The cost of walking away was not zero. Formal consent obtained under conditions of lock-in is a thinner form of consent than the term usually implies.

B.3 The Copyright Assignment Clause: Sun Versus Oracle

Was the copyright assignment ethical under Sun? I would argue: marginally acceptable but poorly designed. Sun had genuine operational reasons for wanting legal clarity over the codebase. In a project of OpenOffice.org's scale, distributed copyright creates real complications — relicensing becomes difficult, licensing disputes require tracking down hundreds of individual contributors. These are not invented problems.

However, Sun could have achieved the same operational goals through a contributor licence agreement — CLA — that granted Sun the rights it needed without transferring ownership. The Linux kernel, the Apache projects, and many others operate on exactly this basis. Sun's choice of full copyright assignment rather than a CLA suggests that something beyond operational necessity was in play: the desire to retain maximum commercial flexibility.

Under Oracle, the same clause became clearly unethical. Oracle's demonstrated willingness to weaponise intellectual property — the Google/Java lawsuit, the commercial Oracle Open Office product — transformed a commercially motivated but arguably tolerable arrangement into something that put contributors at genuine risk. Signing over rights to a company that you know will treat those rights as litigation ammunition is not a reasonable ask of volunteers. The clause did not change; the company holding the rights did, and that transformation changed the ethical calculus entirely.

B.4 Stewardship Versus Ownership: Is There a Real Distinction?

The stewardship/ownership distinction is not merely semantic — it describes two fundamentally different orientations toward a shared resource. A steward holds something in trust for others; an owner holds it for themselves. The question is whether an open source project can be owned in any meaningful sense, or whether ownership always produces eventual betrayal of the community that created value.

I think the LibreOffice story suggests that ownership and open source community health are in long-term tension. A company that owns a project will — rationally, from its shareholders' perspective — optimise for commercial returns. When community interests and commercial interests align, ownership is invisible. When they diverge, ownership wins. The OpenOffice.org community experienced this divergence acutely under Oracle. The solution the Document

Foundation implemented — structural limits on corporate board representation, no copyright assignment, elected leadership — is essentially an institutionalisation of stewardship, converting what had been informal cultural norms into binding governance rules.

The meaningful distinction exists, but it must be enforced structurally. A company that calls itself a steward but retains all governance authority is not a steward; it is an owner using more palatable language. Stewardship without accountability mechanisms is indistinguishable from ownership in practice.

Section C — The Forking Question — Was It the Right Move?

C.1 Were There Better Alternatives?

Before evaluating the fork itself, it is worth asking whether the community exhausted other options. The realistic alternatives were: negotiation with Oracle, continued internal advocacy, or a coordinated contributor slowdown intended to demonstrate leverage.

Negotiation was attempted — the Document Foundation explicitly invited Oracle to donate the OpenOffice.org brand and join the new governance structure. Oracle declined. This was not a failure of diplomacy; it was a rational response from Oracle's perspective. Donating control of an asset it owned to an independent foundation would have removed a commercial advantage Oracle had just paid 7.4 billion dollars to acquire. Internal advocacy had been ongoing for years and had produced no structural change. Contributor slowdowns are effective leverage against companies that depend on community goodwill for recruitment and reputation — Oracle's primary market was enterprise contracts, not developer goodwill. The realistic alternatives to forking were limited.

C.2 Oracle's Refusal — Business Logic Versus Ethical Logic

From a pure business perspective, Oracle's decision to decline the Document Foundation's offer was defensible in the short term. OpenOffice.org had millions of users; Oracle Open Office could be monetised; donating the brand would eliminate a revenue stream. The board of a public company has fiduciary duties to shareholders, and surrendering a commercial asset to community governance would be difficult to justify to investors.

From an ethical perspective, the same decision looks considerably worse. Oracle had acquired OpenOffice.org not through its own creative effort but by purchasing Sun. The value of the project was created overwhelmingly by volunteers who had signed rights to Sun in good faith, not to Oracle. To then retain those rights and monetise the community's labour while simultaneously treating the community as a cost centre rather than a constituency — that is, at minimum, a betrayal of the implicit understanding under which contributions were made.

The business logic and the ethical logic do not produce the same answer. A company can act legally and commercially rationally while still behaving in a way that is ethically questionable. Oracle's handling of OpenOffice.org is a case study in that disjunction.

C.3 The Cost of the Fork — Was It Worth It?

The fragmentation cost of the fork was real and should not be minimised. For several years after 2010, organisations evaluating open source office suites faced a confusing landscape: LibreOffice, Apache OpenOffice, and remnants of the old Oracle-controlled project all existed simultaneously. Users who had become comfortable with OpenOffice.org had to learn new update channels. Linux distributions had to make and communicate a choice. IT departments in governments and universities spent time evaluating something that should have remained stable.

Against this cost must be weighed what not forking would have meant. Apache OpenOffice — the project Oracle eventually donated to Apache in 2011 — provides the counterfactual. It has had minimal major releases and dwindling contributor activity for years. OpenOffice.org without the fork would almost certainly have followed the same trajectory: an increasingly stale codebase, declining community investment, and eventual irrelevance. LibreOffice, by contrast, had over 200 million active users by the early 2020s and a vigorous development community. The fork, despite its short-term costs, was the right long-term decision.

C.4 The Best Case Against Forking

> *Here I construct the strongest possible argument against the fork — not to endorse it, but because intellectual honesty requires engaging with it.*

The anti-fork argument runs as follows: by fragmenting the community, the fork weakened the very thing it sought to protect. A unified OpenOffice.org community, even under Oracle's imperfect stewardship, could have continued to produce valuable software. The fork diverted the energy of the best developers into rebuilding governance infrastructure rather than building features. It confused users at a critical moment when open source office software was gaining institutional traction. And it set a precedent — that communities will abandon projects under corporate control — that may make corporations less willing to invest in open source infrastructure in the future.

Furthermore, the anti-fork argument notes that the community could have stayed and used its leverage more strategically. Oracle needed the community's ongoing contribution to maintain the product's quality. A coordinated campaign of transparency — publicly documenting Oracle's governance failures, lobbying governments and institutions that relied on OpenOffice.org to pressure Oracle — might have achieved structural reform without the costs of fragmentation.

I do not ultimately find this argument persuasive, for two reasons. First, it assumes that Oracle was susceptible to community pressure — but Oracle's business model did not depend on the community's goodwill in the way that a developer-facing company would. Second, the argument asks the community to continue investing labour in a project while Oracle held the IP over their contributions. That is not a sustainable ask. The fork was not a hasty decision; it came after years of internal advocacy that had produced nothing. By 2010, the community had earned the right to conclude that working within the system was not viable.

Section D — Lessons and Generalisation

D.1 Two Forks, One Acquisition: What the Pattern Reveals

The fact that both LibreOffice and MariaDB emerged from Oracle's acquisition of Sun is not a coincidence — it is a signal. Two major, successful open source communities, in different application domains, with different technical cultures, reached the same conclusion: Oracle could not be trusted as a steward. They both forked within roughly the same eighteen-month window.

What this tells us is that community trust is a systemic property, not a project-level one. It depends on the broader reputation and demonstrated behaviour of the controlling entity. MariaDB's creator Michael Widenius did not wait for Oracle to specifically mistreat MySQL; he acted on the known prior of Oracle's IP posture. The LibreOffice founders did not wait for a specific harmful act against OpenOffice.org; they acted on the pattern Oracle had established. Community confidence is fragile and forward-looking — once lost, it does not wait for proof.

The deeper pattern is this: corporate acquisition of companies that serve as open source stewards creates structural risk that cannot easily be mitigated through reassurances. The new owner inherits the IP, the trademark, and the governance authority — but not the community's goodwill, which was built on a relationship with the old owner. If the new owner's culture differs significantly from the old one, community trust will collapse, and no amount of public commitment to community values will restore it if the governance structure remains unchanged.

D.2 The Hypothetical Cloud Company — A Contemporary Analysis

Consider the hypothetical: a large cloud company — call it Company X — contributes the majority of code to a popular open source project, controls its governance, and uses the project's success to drive customers to its commercial services. Is this meaningfully different from the Oracle/OpenOffice.org situation?

In structure, it is similar. In some practical respects, it may be more insidious — because the commercial dependency is less visible. Oracle was openly commercial; the cloud company scenario involves a subtler form of capture. The open source project becomes a funnel for proprietary cloud services. Community labour produces a product that is nominally free but whose most useful form — as a managed service, at scale — is available only through the company's commercial offering.

This pattern is recognisable in the real world: major cloud providers have been accused of 'strip-mining' open source projects — consuming the output of community labour without proportionate contribution, and converting that output into proprietary managed services. Several open source projects have responded by adopting more restrictive licences that prohibit commercial cloud use without separate agreements.

The criteria I would use to evaluate whether a corporate steward can be trusted are:

Governance independence	Can decisions be made without the corporate steward's approval? Is there a meaningful separation between the contributing company and project leadership?
Copyright policy	Does the project require copyright assignment or does it use a contributor licence agreement that preserves contributor ownership?
Commercial alignment	Is the company's commercial interest served by a healthy, independent project, or by a dependent, captive one?
Demonstrated behaviour	Has the company demonstrated restraint when community and commercial interests have conflicted?
Exit cost	How expensive would forking be? The higher the exit cost, the more scrutiny the steward deserves, because the community's practical freedom is limited.

D.3 Governance Recommendations for a New Open Source Project

If I were advising a group of developers starting a new open source project today with ambitions of scale, these are the specific governance structures I would recommend — derived from the LibreOffice case and the subsequent decade of open source governance research.

Foundation structure

Incorporate as an independent non-profit from the outset, not as an afterthought when crisis strikes. The Document Foundation was founded in response to an emergency; ideally it would have existed before Sun handed the project to Oracle. A non-profit entity can hold trademarks, sign contracts, and provide legal clarity without being subordinate to any single commercial interest.

Copyright policy

Never require copyright assignment. Use a contributor licence agreement — the Apache CLA or a project-specific equivalent — that grants the project the rights it needs (relicensing, patent grants) without transferring ownership. Contributors retain their copyright; the project retains operational flexibility. This single change removes the most dangerous element of the OpenOffice.org structure.

Corporate participation limits

Explicitly cap any single company's representation on the governing board — the Document Foundation uses a one-third maximum. Require that at least a majority of the governing board consists of individuals who are not employed by any single corporate contributor. This structurally prevents the scenario where a company acquires a controlling interest by acquiring a single

employer.

Decision-making transparency

All governance decisions — release scheduling, roadmap prioritisation, policy changes — must be made in publicly accessible forums with documented rationale. No significant decision should be made in private channels by a subset of corporate employees. The Apache Software Foundation's model of public mailing list discussion with lazy consensus is a workable template.

Succession planning

Explicitly address what happens if a major contributing organisation is acquired, goes bankrupt, or withdraws support. Who takes over trademark stewardship? Who maintains infrastructure? Having these questions answered in advance, in writing, dramatically reduces the community's vulnerability to the kind of governance shock that triggered the LibreOffice fork.

Section E — Personal Reflection

Before working through this case study, my understanding of open source was mostly technical. I associated it with licensing — GPL, MIT, Apache — and with the practical freedom to download, run, and modify software without paying for it. The word 'community' appeared in my mental model, but it was vague: a group of people somewhere on the internet who cared about code. What I did not have was a clear picture of governance — of who actually makes decisions, who holds the rights, and what happens when those things are misaligned with the community's interests.

Reading this case study changed that. The distinction between legal openness and practical openness struck me as genuinely important, and I am surprised it is not talked about more. We often speak of open source as if the licence is the whole story — as if GPL equals freedom, full stop. But the OpenOffice.org community had a perfectly valid open source licence and still ended up in a situation where thousands of people had effectively donated years of work to a corporation that could — and eventually did — use it however it liked. The licence gave them the right to fork; it did not make forking easy, cheap, or consequence-free.

What surprised me most was not Oracle's behaviour — corporations optimising for shareholder value is not a surprise — but the copyright assignment clause. The idea that a volunteer would sign away ownership of code they wrote, to a company that did not employ them, for a project they worked on in their spare time, seems obviously problematic in retrospect. And yet it was standard practice for years, and many contributors simply did not notice or did not think it mattered. It mattered enormously.

Something in the story that I find genuinely troubling is the asymmetry between the community's contribution and Oracle's gain. The people who built the value of OpenOffice.org were not compensated when Oracle acquired Sun. They did not receive a share of the 7.4 billion dollars. Their labour had been capitalised into an asset that was sold, and they had no say in who bought it. This is not illegal. It may not even be unusual in the broader economy. But it is, I think, genuinely unfair — and it is a kind of unfairness that the open source community has now built structural defences against.

As for whether I would have made the same choice as the LibreOffice founders: I think I would have, but I would not have found it easy. Forking meant walking away from years of investment in a codebase, a user base, and a community — trading momentum for principle. The Document Foundation founders chose principle over convenience, and I admire that, while recognising that not everyone is in a position to make that trade. The developers who stayed with Apache OpenOffice were not wrong to stay; they were in different circumstances, with different constraints.

The LibreOffice story is ultimately about the conditions under which people are willing to build things together — and what it takes to break that willingness. Those conditions are not purely technical. They are about trust, fairness, and the institutions we design to protect both. The open source world built better institutions because of this crisis. That is, perhaps, the most hopeful reading of the story.
